

# Discussion on 31.07.2018

1. Draw an overall average speed box plot for all users and all trajectories
2. Use staypoints within the trajectory lines and between the trajectories. This should be implemented with the time addition approach at both the ends as discussed in previous meeting.
3. Plot both scenarios:
  1. Staypoints only within the trajectories
  2. Staypoints within the trajectories and between the trajectories
4. The distance between the points are actually taken after they snaps to a location. So the difference is the mean distance difference.
